1 | Introduction

Given the opportunity to review the design document and related smart contract source code of the Vabble protocol, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the audited protocol can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

1.1 About Vabble

Vabble provides WEB3 projects and filmmakers with an easy way to finance and distribute WEB3 content such as Films, Series, and Animations. Navigating multiple infrastructures, high upfront costs, and extensive networking make funding WEB3 films and series difficult. Vabble has built a unified WEB3 content financing platform by streamlining the funding process, eliminating upfront costs for creators, studios, and filmmakers, and letting them concentrate on what they do best. Moreover, it developed a WEB3 content distribution infrastructure that brings value to investors and offers a fresh content experience for communities and consumers. The basic information of the audited protocol is as follows:

Table 1.1: Basic Information of Vabble

Item	Description
Name	Vabble
Type	EVM Smart Contract

1.2 About PeckShield

PeckShield Inc. [13] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (<https://t.me/peckshield>), Twitter (<http://twitter.com/peckshield>), or Email (contact@peckshield.com).

Table 1.2: Vulnerability Severity Classification

Impact	High	Critical	High	Medium
	Medium	High	Medium	Low
	Low	Medium	Low	Low
		High	Medium	Low
		Likelihood		

1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [12]:

- Likelihood represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Table 1.3: The Full List of Check Items

Category	Check Item
Basic Coding Bugs	Constructor Mismatch
	Ownership Takeover
	Redundant Fallback Function
	Overflows & Underflows
	Reentrancy
	Money-Giving Bug
	Blackhole
	Unauthorized Self-Destruct
	Revert DoS
	Unchecked External Call
	Gasless Send
	Send Instead Of Transfer
	Costly Loop
	(Unsafe) Use Of Untrusted Libraries
	(Unsafe) Use Of Predictable Variables
	Transaction Ordering Dependence
	Deprecated Uses
Semantic Consistency Checks	Semantic Consistency Checks
Advanced DeFi Scrutiny	Business Logics Review
	Functionality Checks
	Authentication Management
	Access Control & Authorization
	Oracle Security
	Digital Asset Escrow
	Kill-Switch Mechanism
	Operation Trails & Event Generation
	ERC20 Idiosyncrasies Handling
	Frontend-Contract Integration
	Deployment Consistency
	Holistic Risk Management
Additional Recommendations	Avoiding Use of Variadic Byte Array
	Using Fixed Compiler Version
	Making Visibility Level Explicit
	Making Type Inference Explicit
	Adhering To Function Declaration Strictly
	Following Other Best Practices

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- Semantic Consistency Checks: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [11], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings.

1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary
Configuration	Weaknesses in this category are typically introduced during the configuration of the software.
Data Processing Issues	Weaknesses in this category are typically found in functionality that processes data.
Numeric Errors	Weaknesses in this category are related to improper calculation or conversion of numbers.
Security Features	Weaknesses in this category are concerned with topics like authentication, access control, confidentiality, cryptography, and privilege management. (Software security is not security software.)
Time and State	Weaknesses in this category are related to the improper management of time and state in an environment that supports simultaneous or near-simultaneous computation by multiple systems, processes, or threads.
Error Conditions, Return Values, Status Codes	Weaknesses in this category include weaknesses that occur if a function does not generate the correct return/status code, or if the application does not handle all possible return/status codes that could be generated by a function.
Resource Management	Weaknesses in this category are related to improper management of system resources.
Behavioral Issues	Weaknesses in this category are related to unexpected behaviors from code that an application uses.
Business Logics	Weaknesses in this category identify some of the underlying problems that commonly allow attackers to manipulate the business logic of an application. Errors in business logic can be devastating to an entire application.
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used for initialization and breakdown.
Arguments and Parameters	Weaknesses in this category are related to improper use of arguments or parameters within function calls.
Expression Issues	Weaknesses in this category are related to incorrectly written expressions within code.
Coding Practices	Weaknesses in this category are related to coding practices that are deemed unsafe and increase the chances that an exploitable vulnerability will be present in the application. They may not directly introduce a vulnerability, but indicate the product has not been carefully developed or maintained.

2 | Findings

2.1 Summary

Here is a summary of our findings after analyzing the `vabble` implementation. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logic, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings	
Critical	0	
High	0	
Medium	4	
Low	3	
Undetermined	1	
Total	8	

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities that need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in [Section 3](#).

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 4 medium-severity vulnerabilities, 3 low-severity vulnerabilities, and 1 undetermined issue.

Table 2.1: Key Vabble Audit Findings

ID	Severity	Title	Category	Status
PVE-001	Low	Reentrancy Risk Avoidance in FactoryFilmNFT/FactorySubNFT	Time And State	
PVE-002	Medium	Possible Sandwich/MEV For Reduced Returns	Time And State	
PVE-003	Low	No ETH Support in FactoryFilmNFT::mintToBatch()	Business Logic	
PVE-004	Medium	Collusion-Based Revenue Collection With Just-in-Time Film NFTs	Business Logic	
PVE-005	Low	Enforcement of One-Time Initialization in FactoryFilmNFT	Coding Practices	
PVE-006	Medium	Improper Update on Film Fund Raise in FactoryFilmNFT	Business Logic	
PVE-007	Medium	Trust Issue of Admin Keys	Security Features	
PVE-008	Undetermined	Possibly Out-of-Sync Reward Boost in StakingPool	Business Logic	

Beside the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

3 | Detailed Results

3.1 Reentrancy Risk Avoidance in FactoryFilmNFT & FactorySubNFT

- ID: PVE-001
- Severity: Medium
- Likelihood: Medium
- Impact: Medium
- Target: Multiple Contracts
- Category: Time and State [9]
- CWE subcategory: CWE-663 [3]

Description

A common coding best practice in Solidity is the adherence of checks-effects-interactions principle. This principle is effective in mitigating a serious attack vector known as re-entrancy. Via this particular attack vector, a malicious contract can be reentering a vulnerable contract in a nested manner. Specifically, it first calls a function in the vulnerable contract, but before the first instance of the function call is finished, second call can be arranged to re-enter the vulnerable contract by invoking functions that should only be executed once. This attack was part of several most prominent hacks in Ethereum history, including the DAO [15] exploit, and the Uniswap/Lendf.Me hack [14].

We notice there are occasions where the checks-effects-interactions principle is violated. Using the FactoryFilmNFT as an example, the `mint()` function (see the code snippet below) is provided to externally call a token contract to transfer assets. However, the invocation of an external contract requires extra care in avoiding the above re-entrancy. For example, the interaction with the external contract (line 209) start before effecting the update on internal states, hence violating the principle. In this particular case, if the external contract has certain hidden logic that may be capable of launching re-entrancy via the same entry function.

```
180     function mint(  
181         uint256 _filmId,  
182         address _to,  
183         address _payToken
```

```

184     ) public payable {
185         if(_payToken != IOwnablee(OWNABLE).PAYOUT_TOKEN() && _payToken != address(0)) {
186             require(IOwnablee(OWNABLE).isDepositAsset(_payToken), "mint: not allowed
               asset");
187         }
188         require(mintInfo[_filmId].maxMintAmount > 0, "mint: no mint info");
189         require(mintInfo[_filmId].maxMintAmount > getTotalSupply(_filmId), "mint: exceed
               mint amount");
190
191         __handleMintPay(_filmId, _payToken);
192
193         VabbleNFT t = filmNFTContract[_filmId];
194         uint256 tokenId = t.mintTo(_to);
195         filmNFTTokenList[_filmId].push(tokenId);
196
197         emit FilmERC721Minted(address(t), tokenId, _to, block.timestamp);
198     }
199
200     function __handleMintPay(
201         uint256 _filmId,
202         address _payToken
203     ) private {
204         uint256 expectAmount = getExpectedTokenAmount(_payToken, mintInfo[_filmId].price
               );
205         // Return remain ETH to user back if case of ETH and Transfer Asset from buyer
               to this contract
206         if(_payToken == address(0)) {
207             require(msg.value >= expectAmount, "handlePay: Insufficient paid");
208             if (msg.value > expectAmount) {
209                 Helper.safeTransferETH(msg.sender, msg.value - expectAmount);
210             }
211         } else {
212             Helper.safeTransferFrom(_payToken, msg.sender, address(this), expectAmount);
213         }
214         ...
215     }

```

Listing 3.1: FactoryFilmNFT::mint()

Recommendation Apply necessary reentrancy prevention by following the checks-effects-interactions principle and utilizing the necessary `nonReentrant` modifier to block possible re-entrancy. Note the same issue is also applicable another contract `FactorySubNFT`.

Status

3.2 Possible Sandwich/MEV For Reduced Returns

- ID: PVE-002
- Severity: Medium
- Likelihood: Medium
- Impact: Medium
- Target: Multiple Contracts
- Category: Time and State [10]
- CWE subcategory: CWE-682 [4]

Description

To facilitate the user engagement, the `vabbl` protocol supports a variety of payment tokens. Because of that, there is a constant need of swapping one asset to another. With that, the protocol has provided a dedicated helper routine to facilitate the asset conversion. Our analysis shows this swap routine exposes a potential MEV risk.

```

115     function swapAsset(bytes calldata _swapArgs) external transferHandler(_swapArgs)
116         returns (uint256 amount_) {
117         (
118             uint256 depositAmount,
119             address depositAsset,
120             address incomingAsset
121         ) = abi.decode(_swapArgs, (uint256, address, address));
122
123         (address router, , address weth, address[] memory path) = __checkPool(
124             depositAsset, incomingAsset);
125         require(router != address(0), "swapAsset: No Pool");
126
127         // Get payoutAmount from depositAsset on Uniswap
128         uint256 expectAmount = IUniswapV2Router(router).getAmountsOut(depositAmount,
129             path)[1];
130
131         if(path[0] == weth) {
132             amount_ = __swapETHToToken(depositAmount, expectAmount, router, path)[1];
133         } else {
134             amount_ = __swapTokenToToken(depositAmount, expectAmount, router, path)[1];
135         }
136     }

```

Listing 3.2: UniHelper::swapAsset()

To elaborate, we show above the related helper routine. We notice the conversion is routed to `UniswapV2/SushiSwap` in order to swap one asset to another. While the swap operation does specify the expected amount for slippage control, the expected amount calculation does not present to be manipulation-resistant and is therefore vulnerable to possible front-running attacks, resulting in a smaller gain for this round of conversion.

Note that this is a common issue plaguing current AMM-based DEX solutions. Specifically, a large trade may be sandwiched by a preceding sell to reduce the market price, and a tailgating buy-back

of the same amount plus the trade amount. Such sandwiching behavior unfortunately causes a loss and brings a smaller return as expected to the trading user because the swap rate is lowered by the preceding sell. As a mitigation, we may consider specifying the restriction on possible slippage caused by the trade or referencing the TWAP or time-weighted average price of UniswapV2. Nevertheless, we need to acknowledge that this is largely inherent to current blockchain infrastructure and there is still a need to continue the search efforts for an effective defense.

Recommendation Develop an effective mitigation (e.g., slippage control) to the above front-running attack to better protect the interests of farming users. Note this issue affects a number of routines that rely on the above token swap routine.

Status

3.3 No ETH Support in FactoryFilmNFT::mintToBatch()

- ID: PVE-003
- Severity: Low
- Likelihood: Low
- Impact: Low
- Target: FactoryFilmNFT
- Category: Business Logic [8]
- CWE subcategory: CWE-841 [5]

Description

The Vabble protocol has a FactoryFilmNFT contract to allow for user funding via file-related NFT mints. In the process of reviewing current mint logic, we notice the batch minting does not support the ETH payment.

To elaborate, we show below the implementation of the `mintToBatch()` routine. This routine is designed to mint a given batch of NFTs. Note actual mint of each individual NFT is delegated to the `mint()` routine. However, it comes to our attention that this `mintToBatch()` routine does not have the `payable` modifier, while the `mint()` counterpart does have it. In other words, current implementation of `mintToBatch()` does not support ETH as the payment token.

```

167     function mintToBatch(
168         uint256[] calldata _filmIdList,
169         address[] calldata _toList,
170         address _payToken
171     ) external {
172         require(_toList.length > 0, "mintBatch: zero item length");
173         require(_toList.length == _filmIdList.length, "mintBatch: bad item length");
174
175         for(uint256 i; i < _toList.length; i++) {
176             mint(_filmIdList[i], _toList[i], _payToken);
177         }

```

```

178     }
179
180     function mint(
181         uint256 _filmId,
182         address _to,
183         address _payToken
184     ) public payable {
185         if(_payToken != IOwnablee(OWNABLE).PAYOUT_TOKEN() && _payToken != address(0)) {
186             require(IOwnablee(OWNABLE).isDepositAsset(_payToken), "mint: not allowed
187                 asset");
188         }
189         require(mintInfo[_filmId].maxMintAmount > 0, "mint: no mint info");
190         require(mintInfo[_filmId].maxMintAmount > getTotalSupply(_filmId), "mint: exceed
191             mint amount");
192
193         __handleMintPay(_filmId, _payToken);
194
195         VabbleNFT t = filmNFTContract[_filmId];
196         uint256 tokenId = t.mintTo(_to);
197         filmNFTTokenList[_filmId].push(tokenId);
198
199         emit FilmERC721Minted(address(t), tokenId, _to, block.timestamp);
200     }

```

Listing 3.3: FactoryFilmNFT::mintToBatch()

Recommendation Revise the above routine to allow for the use of ETH as the payment token.

Status

3.4 Collusion-Based Revenue Collection With Just-in-Time Film NFTs

- ID: PVE-004
- Severity: Medium
- Likelihood: Medium
- Impact: Medium
- Target: VabbleDAO
- Category: Coding Practices [7]
- CWE subcategory: CWE-563 [2]

Description

To facilitate the protocol management, the Vabble protocol has a built-in VabbleDAO support. To encourage user participation, VabbleDAO is designed to transfer certain revenue amount to the user if the user funds this film throughout NFT mints. In the process of reviewing the revenue refund logic, we notice the implementation can be improved.

To elaborate, we show below the implementation of the related `__payRevenue()` function. This function counts the total number of owned NFT mints in `nftCountOwned` and then computes the revenue as `revenueAmount = nftCountOwned * _payout * revenuePercent / 1e10` (line 369). This logic may be susceptible to a collusion attack where multiple users may share their NFT mints so that each may maximize his/her revenue return.

```

356     function __payRevenue(
357         address _user,
358         address _vabToken,
359         uint256 _filmId,
360         uint256 _payout
361     ) private {
362         uint256 nftCountOwned;
363         uint256[] memory nftList = IFactoryFilmNFT(FILM_NFT_FACTORY).getFilmTokenIdList(
            _filmId);
364         for(uint256 i = 0; i < nftList.length; i++) {
365             if(IErc721(FILM_NFT_FACTORY).ownerOf(nftList[i]) == _user) nftCountOwned +=
                1;
366         }
367
368         ( , , , , uint256 revenuePercent, , ) = IFactoryFilmNFT(FILM_NFT_FACTORY).
            getMintInfo(_filmId);
369         uint256 revenueAmount = nftCountOwned * _payout * revenuePercent / 1e10;
370         if(_payout >= revenueAmount && revenueAmount > 0) {
371             require(StudioPool >= revenueAmount, "revenue: insufficient studio pool");
372             require(IErc20(_vabToken).balanceOf(address(this)) >= revenueAmount, "
                revenue: insufficient balance");
373
374             Helper.safeTransfer(IOwnablee(OWNABLE).PAYOUT_TOKEN(), _user, revenueAmount)
                ;
375             StudioPool -= revenueAmount;
376         }
377     }

```

Listing 3.4: VabbleDAO::__payRevenue()

Recommendation Revisit the above routine to properly compute the revenue reward in a robust manner.

Status

3.5 Enforcement of One-Time Initialization in FactoryFilmNFT

- ID: PVE-005
- Severity: Low
- Likelihood: Low
- Impact: Low
- Target: FactoryFilmNFT
- Category: Coding Practices [7]
- CWE subcategory: CWE-563 [2]

Description

As mentioned earlier, the Vabble protocol has a FactoryFilmNFT contract to allow for user funding via file-related NFT mints. While reviewing the logic to initialize the film-related mint information, we notice the initialization routine may be repeatedly invoked, which should be revised to be invoked once.

To elaborate, we show below the implementation of the `setMintInfo()` routine. This routine is protected to be invoked only by the film owner. However, it comes to our attention that it may be repeatedly invoked. With that, we suggest to take necessary measures to ensure it will be only invoked once for each film.

```

103     function setMintInfo(
104         uint256 _filmId,
105         uint256 _tier,
106         uint256 _amount,
107         uint256 _price,
108         uint256 _feePercent,
109         uint256 _revenuePercent
110     ) external {
111         require(_amount > 0 && _price > 0 && _tier > 0, "setMint: Zero value");
112         require(_feePercent <= IProperty(DAO_PROPERTY).maxMintFeePercent(), "setMint:
            over max mint fee");
113         require(_revenuePercent < 1e10, "setMint: over 100%");
114
115         address owner = IVabbleDAO(VABBLE_DAO).getFilmOwner(_filmId);
116         require(owner == msg.sender, "setMint: not film owner");
117
118         (uint256 raiseAmount, , uint256 fundType) = IVabbleDAO(VABBLE_DAO).getFilmFund(
            _filmId);
119         if(fundType > 0) { // case of funding film
120             require(_amount * _price * (1e10 - _feePercent) / 1e10 > raiseAmount, "
                setMint: many amount");
121         }
122
123         Mint storage mInfo = mintInfo[_filmId];
124         mInfo.tier = _tier; // 1, 2, 3, , ,
125         mInfo.maxMintAmount = _amount; // 100
126         mInfo.price = _price; // 5 usdc = 5 * 1e6
127         mInfo.feePercent = _feePercent; // 2% = 2 * 1e8 (1% = 1e8, 100% = 1e10)

```

```

128     mInfo.revenuePercent = _revenuePercent; // any %(1% = 1e8, 100% = 1e10)
129     mInfo.studio = msg.sender;
130
131     emit MintInfoSetted(msg.sender, _filmId, _tier, _amount, _price, _feePercent,
132         _revenuePercent, block.timestamp);
133 }

```

Listing 3.5: FactoryFilmNFT::setMintInfo()

Recommendation Only allow for one-time initialization of the above `setMintInfo()` routine for each film. Also, the same issue is also applicable to another `deployFilmNFTContract()` routine.

Status

3.6 Improper Update on Film Fund Raise in FactoryFilmNFT

- ID: PVE-006
- Severity: Low
- Likelihood: Low
- Impact: Low
- Target: FactoryFilmNFT
- Category: Business Logic [8]
- CWE subcategory: CWE-841 [5]

Description

As mentioned in Section 3.3, `vabble` allows users to mint `Film` NFTs to fund the film production. Naturally, the `FactoryFilmNFT` contract keeps track of the raised funds for each film. While examining internal accounting logic, we notice the current implementation does not properly keep track of the fund raise amount for each film.

To elaborate, we show below the implementation of the related `mint()` routine. It has a rather straightforward logic in collecting the payment and minting the associated film NFT. However, it forgot to update the accumulated fund raise with the following statement: `fileFundRaisedByNFT[_filmId] += mintInfo[_filmId].price`.

```

180     function mint(
181         uint256 _filmId,
182         address _to,
183         address _payToken
184     ) public payable {
185         if(_payToken != IOwnablee(OWNABLE).PAYOUT_TOKEN() && _payToken != address(0)) {
186             require(IOwnablee(OWNABLE).isDepositAsset(_payToken), "mint: not allowed
187                 asset");
188         }
189         require(mintInfo[_filmId].maxMintAmount > 0, "mint: no mint info");
190         require(mintInfo[_filmId].maxMintAmount > getTotalSupply(_filmId), "mint: exceed
191             mint amount");

```

```

190
191     __handleMintPay(_filmId, _payToken);
192
193     VabbleNFT t = filmNFTContract[_filmId];
194     uint256 tokenId = t.mintTo(_to);
195     filmNFTTokenList[_filmId].push(tokenId);
196
197     emit FilmERC721Minted(address(t), tokenId, _to, block.timestamp);
198 }

```

Listing 3.6: FactoryFilmNFT::mint()

Recommendation Revisit the above routine to properly update the accumulated fund raise for each film.

Status

3.7 Trust Issue of Admin Keys

- ID: PVE-007
- Severity: Medium
- Likelihood: Medium
- Impact: Medium
- Target: Multiple Contracts
- Category: Security Features [6]
- CWE subcategory: CWE-287 [1]

Description

In the vabble protocol, there is a privileged auditor account that plays a critical role in governing and regulating the protocol-wide operations (e.g., parameter configuration and sensitive operation execution). Our analysis shows that this privileged account needs to be scrutinized. In the following, we use the Ownable contract as an example and show the representative functions potentially affected by the privileges of the auditor account.

```

56     function setup(
57         address _vote,
58         address _dao,
59         address _stakingPool
60     ) external onlyAuditor {
61         require(_vote != address(0), "setupVote: bad Vote Contract address");
62         VOTE = _vote;
63         require(_dao != address(0), "setupVote: bad VabbleDAO contract address");
64         VABBLE_DAO = _dao;
65         require(_stakingPool != address(0), "setupVote: bad StakingPool contract address");
66         STAKING_POOL = _stakingPool;
67     }

```

```

69     function transferAuditor(address _newAuditor) external onlyAuditor {
70         require(_newAuditor != address(0) && _newAuditor != auditor, "Ownable: Zero
           newAuditor address");
71         auditor = _newAuditor;
72     }

74     function replaceAuditor(address _newAuditor) external onlyVote {
75         require(_newAuditor != address(0) && _newAuditor != auditor, "Ownable: Zero
           newAuditor address");
76         auditor = _newAuditor;
77     }

79     function addDepositAsset(address[] calldata _assetList) external onlyAuditor {
80         require(_assetList.length > 0, "addDepositAsset: zero list");

82         for(uint256 i = 0; i < _assetList.length; i++) {
83             if(allowAssetToDeposit[_assetList[i]]) continue;

85             depositAssetList.push(_assetList[i]);
86             allowAssetToDeposit[_assetList[i]] = true;
87         }
88     }

90     function removeDepositAsset(address[] calldata _assetList) external onlyAuditor {
91         require(_assetList.length > 0, "removeDepositAsset: zero list");

93         for(uint256 i = 0; i < _assetList.length; i++) {
94             if(!allowAssetToDeposit[_assetList[i]]) continue;

96             for(uint256 k = 0; k < depositAssetList.length; k++) {
97                 if(_assetList[i] == depositAssetList[k]) {
98                     depositAssetList[k] = depositAssetList[depositAssetList.length - 1];
99                     depositAssetList.pop();

101                     allowAssetToDeposit[_assetList[i]] = false;
102                 }
103             }

105         }
106     }

```

Listing 3.7: Example Privileged Operations in Ownable

We understand the need of the privileged functions for proper contract operations, but at the same time the extra power to the privileged account may also be a counter-party risk to the contract users. Therefore, we list this concern as an issue here from the audit perspective and highly recommend making these privileges explicit or raising necessary awareness among protocol users.

Recommendation Promptly transfer the administrative privileges to the intended DAO-like governance contract. And activate the normal on-chain community-based governance life-cycle and

ensure the intended trustless nature and high-quality distributed governance.

Status

3.8 Possibly Out-of-Sync Reward Boost in StakingPool

- ID: PVE-008
- Severity: Medium
- Likelihood: Medium
- Impact: Medium
- Target: StakingPool
- Category: Coding Practices [7]
- CWE subcategory: CWE-563 [2]

Description

To facilitate the protocol engagement, the `vabble` protocol has a built-in `StakingPool` support. Users may stake `VAB` tokens to receive rewards. Moreover, to encourage users to participate in the protocol governance, the reward may be boosted with the governance involvement. In the process of reviewing the reward boost logic, we notice the current approach needs to be revisited.

To elaborate, we show below the implementation of the related `calcRewardAmount()` function. This function calculates the staking reward amount for the given user. We notice the computed reward amount is amplified with a factor, i.e., `rewardAmount * voteCount / proposalCount`, where `voteCount` represents the total number of voted protocols by the user and `proposalCount` denotes the number of protocols which are active during the user staking time period. As a result, these two states `voteCount` and `proposalCount` may be out-of-sync with respect to the staker lifetime.

```

197     function calcRewardAmount(address _customer) public view returns (uint256 amount_) {
198         Stake memory si = stakeInfo[_customer];
199         require(si.stakeAmount > 0, "calcRewardAmount: Not staker");
200
201         uint256 minAmount = 10**IERC20Metadata(IOwnablee(OWNABLE).PAYOUT_TOKEN()).
                decimals() / 100;
202         require(si.stakeAmount > minAmount, "calcRewardAmount: less amount than 0.01");
203
204         // Get proposal count started in withdrawable period of customer
205         uint256 proposalCount = 0;
206         for(uint256 i = 0; i < proposalCreatedTimeList.length; i++) {
207             if(proposalCreatedTimeList[i] > si.stakeTime && proposalCreatedTimeList[i] <
                si.withdrawableTime) {
208                 proposalCount += 1;
209             }
210         }
211
212         uint256 rewardPercent = __rewardPercent(si.stakeAmount); // 0.0125*1e8 = 0.0125%
213
214         // Get time with accuracy(10**4) from after lockPeriod

```

```
215     uint256 period = (block.timestamp - si.stakeTime) * 1e4 / 1 days;
216     uint256 rewardAmount = totalRewardAmount * rewardPercent * period / 1e10 / 1e4;
217
218     // if no proposal then full rewards, if no vote for 5 proposals then no rewards,
219     // if 3 votes for 5 proposals then rewards*3/5
220     if(proposalCount > 0) {
221         if(si.voteCount == 0) {
222             rewardAmount = 0;
223         } else {
224             uint256 countVal = (si.voteCount * 1e4) / proposalCount;
225             rewardAmount = rewardAmount * countVal / 1e4;
226         }
227
228         // If customer is film board member, more rewards(25%)
229         if(IProperty(DAO_PROPERTY).isBoardWhitelist(_customer) == 2) {
230             rewardAmount = rewardAmount + rewardAmount * IProperty(DAO_PROPERTY).
231                 boardRewardRate() / 1e10;
232         }
233
234         amount_ = rewardAmount;
235     }
```

Listing 3.8: StakingPool::calcRewardAmount()

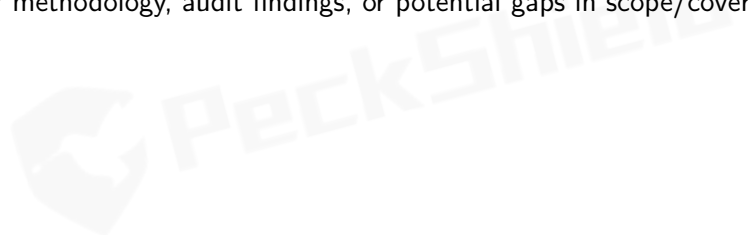

Recommendation Revisit the above routine to properly compute the boost factor for the staking reward.

Status

4 | Conclusion

In this audit, we have analyzed the design and implementation of the `vabble` protocol, which provides `WEB3` projects and filmmakers with an easy way to finance and distribute `WEB3` content such as `Films`, `Series`, and `Animations`. Navigating multiple infrastructures, high upfront costs, and extensive networking make funding `WEB3` films and series difficult. `vabble` has built a unified `WEB3` content financing platform by streamlining the funding process, eliminating upfront costs for creators, studios, and filmmakers, and letting them concentrate on what they do best. Moreover, it developed a `WEB3` content distribution infrastructure that brings value to investors and offers a fresh content experience for communities and consumers. The current code base is well structured and neatly organized. Those identified issues are promptly confirmed and addressed.

Meanwhile, we need to emphasize that smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
